CIRCUIT DESCRIPTION

COMPUTER BOARD GL-10

The uPD8048 is an 8-bit parallel computer fabricated on a single sillicon chip. The 8048 contains a 1k x 8 ROM program memory, a 64 x 8 RAM memory, 27 I/O lines, an 8-bit timer/counter and clock circuits.
Used on this board is a uPD8048C-015 version in which program and data dedicated to the CR-68 are stored in the program memory.

1. SCANNING for IDENTIFYING PANEL SWITCH SETTINGS

The uPD8048 reads panel switch settings by scanning the lines through Port 2 (P24-P27) of IC10, IC8 (74LS-138, Decoder) and Port 1 (P10-P17) of IC10. The output from IC8 (Binary-to-octal decoder) goes through one of properly arranged switches and matrix to port 1. For example let's assume that SWING switch is depressed. When A input of IC8 is high and B, C and G2B inputs are low as shown in Fig. 1. The output of 1 goes low and other outputs go high.
Since Port 1 (P10-P17) functions now as an input port and 1 of IC8 is low with SWING switch on, only P10 of IC10 goes low. IC10 reads this condition of Port 1 and identifies that SWING switch is depressed. By repeating such scanning, the computer can identify every switch setting in sequence.
This scanning and reading, in STOP mode, are performed continously in very short periods by pulses with durations of several microsecons, bur after START switch is pressed, this scanning is performed once a measure

2. SENDING OUT RHYTHM PATTERNS

After panel settings are identified as described above, the data corresponding to the identification is selected from contains of the ROM and fed into Port 1 and Port 2.
Tow 74LS138's (IC8 and IC9) are used in parallel to constitute a binary-to-hexadecimal decoder. In this case, Port 1 of IC10 functions as an output port.

3. VARIATION TURNED ON WITH MANUAL BUTTON

Since the computer reads data once in one measure, if MANUAL button is pressed during the period between one reading and another, a circuit is required to memorize the switching, which consists of IC4 (74LS00) and other components.
IC4a and IC4b constitute an RS flip-flop which is reset when START/STOP button is tapped to start the rhythm unit. When reset in this way, pin 3 of IC4a goes high, and pin 6 of IC4b goes low and hereafter this condition is held.
In reading, with MANUAL button off, pin 6 of IC4b remains low and pin 8 of IC4c is held high independent of the condition of pin 10 of IC4c. When MANUAL button is pressed, pin 5 of IC4b immediately goes low and RS flip-flop is set. Pin 3 of IC4a goes low and pin 6 of IC4b goes high and this condition is

When a negative going pulse is sent out from 4 of IC8 while reading switch positions, the pulse is inverted by IC2c and this inverted positive pulse is fed to pin 10 of IC4c. Since pin 9 of IC4c is kept high, a negative going pulse is sent out from pin 8 of IC4c and fed into Port 1 through D209. Thus, the computer detects that MANUAL button has been pressed.
Immediately after reading, the computer sends out a negative going pulse from 0 of IC8 to reset RS flip-flop. To prevent malfunction, this pulse (after invertion by IC2a) and a pulse from ALE of IC10 are NANDed to produce a reset pulse. see Fig. 2

4. CLOCK GENERATOR IC3e, IC3f

This circuit,a clock generator from which pulses are emitted to synchronize the operations carried out by the computer, is a CR oscillator consisting of IC3e, IC3f and other components. The oscillator generates clock signals of about 3MHz which are fed to XTAL pin of IC10.

5. MASTER OSCILLATOR Q101, Q102

This oscillator determines the tempo of the rythm and is a multivibrator consisting of Q101, Q102 and other components, whose oscillation period is variable from 10ms - 200ms with TEMPO control VR2.

6. START CIRCUIT IC5b, IC1a - IC1d, IC2b

This circuit consists of IC5b (D flip-flop) and other components. The output "Q" on pin 1 of IC5b is connected to T1 of IC10.
Immediately after POWER switch is set to ON a short positive going pulse with the time constant of R212 and C208 is generated at pin 11 of IC1d and resets IC5b. Q on pin 1 goes low and $\overline{Q}$ on pin 2 goes high. Consequently, when POWER switch is set to ON, IC10 is always set in the idling mode.(When T1 of IC10 is low, the computer stops all functions except scanning).
When START button is pressed, a positive pulse is generated at pin 4 of IC1b which is fed into pin 3 of IC5b. Q goes high and $\overline{Q}$ goes low. Then T1 of IC10 goes high to start the rhythm unit.
The one shot pulse generator consisting of IC1a, IC1c, IC2b and other components detects the leading edge of an output waveform from Q on pin 1 of IC5b and generates a pulse with a duration of about 30ms which resets the master oscillator when the rhythm unit starts. see Fig. 3

7. FOOT SWITCH CIRCUIT IC3a - IC3d

The foot switch circuit for START/STOP consisting of IC3a, IC3b and other components, and that for VARIATION consisting of IC3c,IC3d and other components,are almost the same circuit. A CR time constant circuit combined with a schmitt trigger circuit is used to prevent malfunction caused by foot switch chattering.

8. DIVIDER IC7a, IC5a, IC6a, IC6b

To send out clock pulses with 8 beat and 16 beat to TRIGGER OUT jack, a circuit is required to divide the output signals from the master oscillator into 1/3 and 1/6. The circuit consists of four MC14013B's (D flip-flop, IC7a, IC5a, IC6a, and IC6b) and other components. IC7a, used as an inverter, shapes output waveforms from the master oscillator to prevent the divide-by-3 circuit from malfunctioning. The singals are fed into the divide-by-3 circuit consisting of IC5a and IC6b to be converted to signals with 16 beat and sent from Q on pin 1 of IC6b.
Signals fed from $\overline{Q}$ on pin 2 of IC6b to CP on pin 11 of IC6a are divided again to be converted to signals with 8 beat and sent out from Q on pin 13 of IC6a.
see Fig.4

VOICING BOARD VG-12

1. LATCH IC1 -- IC3

This circuit,consisting of three 74LS175 flip-flops, take output pulses to be latched from Port 1 and Port 2 through IC2d and IC2e (clock), and take pulses from the master oscillator to clear the preceding latch, producing 5V positive going pulse, i.e. rhythm pattern, with the same duration as output pulse of the master oscillator.
The output pulses from the flip-flops are converted by Q25-Q35 into negative going pulses with a +15V-0V swing and fed into inputs of the voicing circuits.
see Fig. 5

2. ACCENT CIRCUIT Q21, Q24, VR14

This circuit is used to add accent to a rhythm according to a preset accent pattern by changing the sound level at the output amplifier. The circuit consists of the ACCENT (VR14), Q21, Q24 and other components. An accent pulse from $\overline{Q}$ on pin 3 of IC1 passes through Q21 and then is differentiated and intergrated to be converted to a proper envelope signal which is fed into the gate of FET (Q24).
Q24 is off when a signal is not provided at the gate. In this case, the voltage of the output signal from Q9 is divided by the ratio of R137 (68k-ohm) to the input impedance of Q10 and is fed into Q10. When a signal is fed into the gate, Q24 is turned on.
With ACCENT control at 10, most the signal flows into the accent potentiometer and Q24, but very little into R137, giving a high level output signal which is used to add accent.

3. LEAKAGE SOUND KILLER Q20, Q23

These circuits are designed to kill sound from the voicing circuits generated by transient voltage when power is turned on or off. When power is on, Q20 will not function normally until C79 charges enough in respect to the emitter.
The voltage drop at the gate of Q23 is quicker than it is at the drain or source after trun, so that Q23 is shut off.

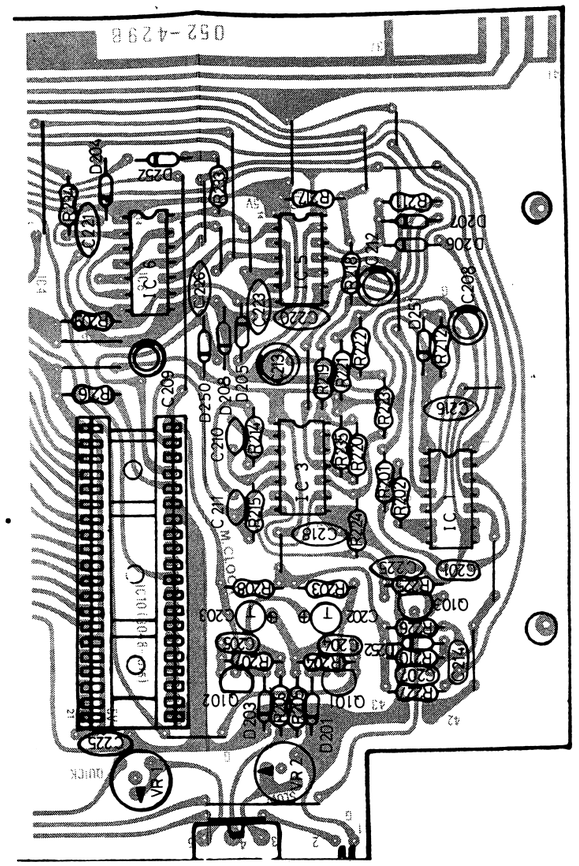
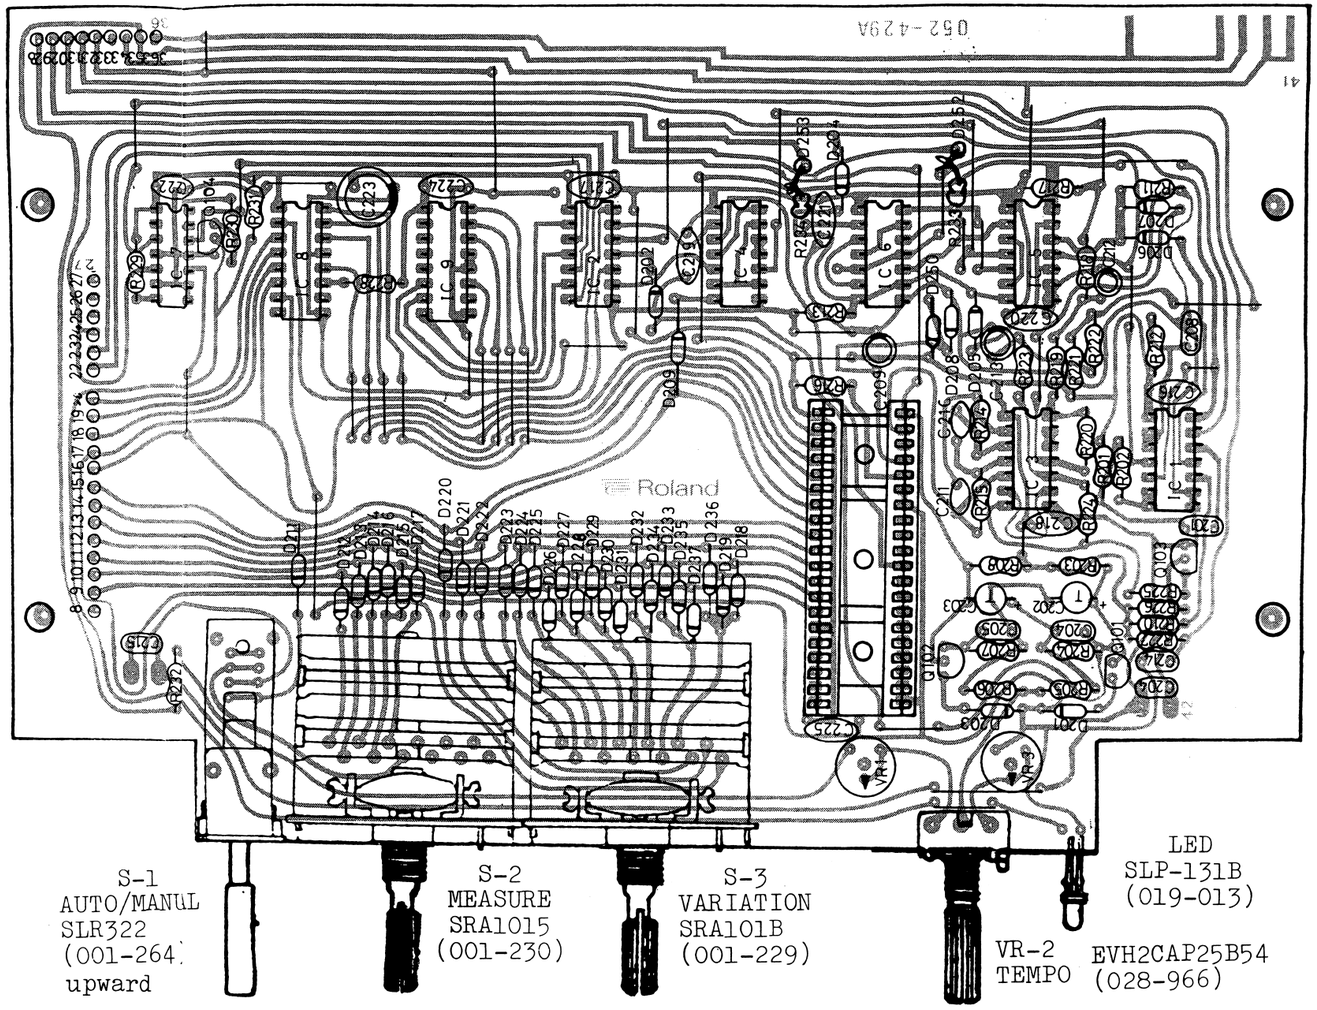
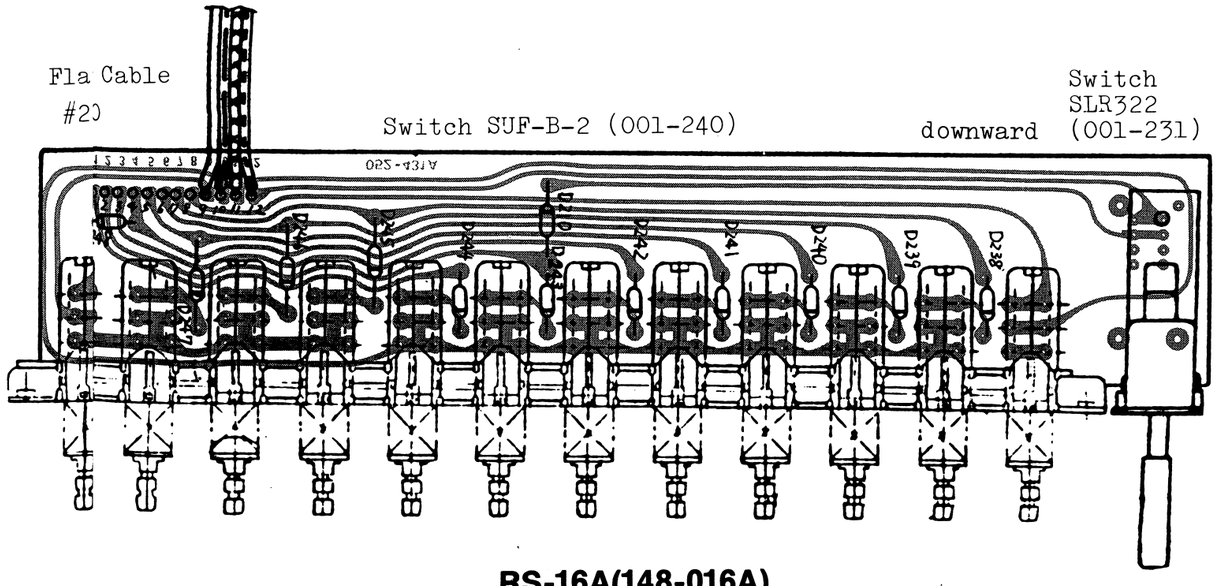
GL-10B(142-010B) VIEW from FOIL SIDE Serial No.822000 and up



Portions of pattern not shown remain unchanged.

Both GL-10A and GL-10B correspond to the same circuit diagram since some components are attached on the foil side or connected in series in the form of pyramid on GL-10A and accommodated on GL-10B in place.

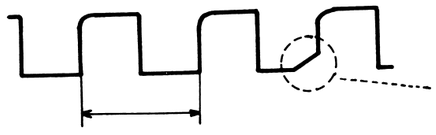




CAUTION: Always handle MOS ICs while wearing an earth grounded wristband to prevent failure of ICs due to electrostatic discharge. All test equipment must also be earth grounded.

RHYTHM TEMPO ADJUSTMENT

1. Connect scope to Q102 collector (Master Oscillator).
2. Turn TEMPO knob full clockwise (QUICK).
   Adjust VR1 for 10ms between fall or rise of squares.
3. Turn TEMPO knob full counterclockwise (SLOW).
   Turn VR3 in the direction in which the period becomes shorter than 200ms. Stop, then rotate VR3 slowly in the reverse direction until the period is 200ms.
4. Repeat steps 3 and 4.



10msec (QUICK)
200msec (SLOW)

If bottom portion is insuficiently saturated, replece Q101 and Q102 with a new pair of the same rank.
